

CS251 Fall 2023

(cs251.stanford.edu)

Stablecoins & Lending Protocols

Dan Boneh

Recap: Solidity

Everything is a contract:

- Contracts manage state variables
- Contracts have functions that can be called externally
- Can inherit code from other contracts (contract A is B,C)
- Types of contracts: contract, interface, abstract, library

Global objects: block, msg, tx

An example: ERC20 tokens

- <u>https://github.com/ethereum/EIPs/blob/master/EIPS/eip-20.md</u>
- A standard API for <u>fungible tokens</u>. (ERC-721 for non-fungible tokens)
- An ERC20 token is itself a smart contract that maintains all user balances:

mapping(address => uint256) internal _balances;

• A standard interface allows other contracts to interact with every ERC20 token. No need for special logic for each token.

ERC20 token interface

function **transfer**(address _to, uint256 _value) external returns (bool);

function transferFrom(address _from, address _to, uint256 _value) external returns (bool);

function **approve**(address _spender, uint256 _value) external returns (bool);

function **totalSupply**() external view returns (uint256);

function **balanceOf**(address _owner) external view returns (uint256);

function **allowance**(address _owner, address _spender) external view returns (uint256);

An example ...

Consider two ERC-20 tokens: say USDC and WETH

- USDC is a contract that maintains a _balances[] mapping
- WETH is a different contract that also maintains _balances[]

Say Bob owns 5 USDC and 2 WETH. This is recorded as:

- In USDC contract: _balances[Bob's address] == 5
- In WETH contract: _balances[Bob's address] == 2

Wallet software shows all the coins associated with Bob's address

Anyone can read ERC20 _balances[]

Transaction Hash: 0x6b85ca95e484d94503d1276456bfc32cc55f6fdb8bb231ff83....

Tells the USDC contract to transfer 10,010.00 USDC from Circle's account to 0x7656159E42209A95b77aD374d...

(etherscan.io)

Calling other contracts

Addresses can be cast to contract types.

address _usdc = 0x7656159E42209A95b77aD374d...;

ERC20Token usdcContract = ERC20Token(_usdc);

To call the "transfer" function of contract at address _usdc: usdcContract.transfer(_to, _value);

The world of DeFi

on-chain contracts

The world of DeFi

on-chain contracts

DeFi app #1: Stablecoins

Stable Coins

A cryptocurrency designed to trade at a fixed price

• Examples: **1 coin = 1 USD**, 1 coin = 1 EUR, 1 coin = 1 USDX

Goals:

- Integrate real-world currencies into on-chain applications
- Enable people without easy access to USD, to hold and trade a USD-equivalent asset

Types of stable coins

	centralized	algorithmic
collateralized	custodial stablecoins (USD Coin)	synthetics (DAI, RAI)
Un(der)collateralized	central bank (digital) currency	Undercollateralized stablecoins

Custodial stablecoins: minting

Custodial stablecoins: transfers

Custodial stablecoins: withdrawal

Two Examples

	Coins issued	24h volume
USDC	25.3 B	4.6 B
USDT	83.7 B	20.8 B

Some issues

Custodian keeps treasury in a traditional bank

- Must be audited to ensure treasury is available
- Earns interest on deposits

Custodian has strong powers:

- Can freeze accounts / refuse withdrawal requests
- Custodian can remove funds from user balances

Collateralized Decentralized Stablecoins

Goal: a stablecoin with no trusted parties

Examples: DAI, RAI, and others.

Not as widely used as centralized stablecoins

DeFi app #2: Lending Protocols

Goal: explain how decentralized lending works

This is not investment or financial advice

The role of banks in the economy

Banks bring together lenders and borrowers

The role of banks in the economy

Crypto: CeFilending (e.g., Blockfi, Nexo, ...)

Same as with a traditional bank:

Alice gives her assets to the CeFi institution to lend out to Bob

(1 ETH = 100 UNI)

CeFi's concern: what if Bob defaults on loan?

 \implies CeFi will absorb the loss

Solution: require Bob to lock up collateral

Several things can happen next:

(1) Bob repays loan

(1 ETH = 100 UNI)

(1 ETH = 400 UNI)

Several things can happen next:

- (1) Bob repays loan
- (2) Bob defaults on loan
- (3) Liquidation: value of loan increases relative to collateral

lender needs to liquidate **before** value(debt) > value(collateral)

Terminology

Collateral: assets that serve as a security deposit

Over-collateralization: borrower has to provide value(collateral) > value(loan)

Under-collateralization: *value(collateral) < value(loan)*

Liquidation:

collateral factor

if value(debt) $> 0.6 \times$ value(collateral)

then collateral is liquidated until inequality flips (liquidation reduces both sides of the inequality)

Collateral factor

CollateralFactor \in [0,1]

- Max value that can be borrowed using this collateral
- High volatility asset \implies low collateral factor
- Relatively stable asset \implies higher collateral factor

<u>Examples:</u> (on Compound) ETH, DAI: 83%, UNI: 75%, MKR: 73%

Health of a debt position

BorrowCapacity =
$$\sum_{i}$$
 value(collateral_i) × CollateralFactor_i
(in ETH)

$$health = \frac{BorrowCapacity}{value(TotalDebt)}$$

helath < 1 \implies triggers liquidation until (health \ge 1)

Example: Aave dashboard (a DeFi lending Dapp)

Credit: Arthur Gervais

If Bob has collateral, why can't he just buy ETH?

- Bob may need ETH (e.g., to buy in-game assets), but he might not want to sell his collateral (e.g., an NFT)
- As an investment strategy: using UNI to borrow ETH gives Bob exposure to both

The problem with CeFi lending

Users must trust the CeFi institution:

- Not to get hacked, steal assets, or miscalculate
- This is why traditional finance is regulated
- Interest payments go to the exchange, not liquidity provider Alice
- CeFi fully controls spread (borrow interest deposit interest)

DeFi Lending

Can we build an on-chain lending Dapp?

- \Rightarrow no central trusted parties
- \Rightarrow code available on Ethereum for inspection

A first idea: an order book Dapp

Credit: Eddy Lazzarin

Challenges

- **Computationally expensive**: matching borrowers to lenders requires many transactions per person (post a bid, retract if the market changes, repeat)
- **Concentrated risk**: lenders are exposed to their direct counterparty defaulting
- **Complex withdrawal**: a lender must wait for their counter-parties to repay their debts

A better approach: liquidity pools

Over-collateralized lending: Compound and Aave

Example: Compound cTokens

Value of X, Y, Z is determined by the current exchange rate: Token to cToken exchange rate is calculated every block

Borrowers

Bob's accrued interest increases ETH/cETH exchange rate

 \implies benefit cETH token holders (ETH liquidity providers)

The exchange rate

Consider the ETH market:

Supplying ETH:adds to UnderlyingBalance
ETHBorrowing ETH:adds to totalBorrowBalance
ETHInterest:added repeatedly to totalBorrowBalance
FTH

ExchangeRate=	UnderlyingBalance _{ETH} + totalBorrowBalance _{ETH} – reserve _{ETH}
	cTokenSupply _{ETH}

⇒ As totalBorrowBalance increases so does ExchangeRate

The interest rate: constantly updates

Key idea: determined by demand for asset vs. asset market size

Utilization ratio:
$$U_{ETH} = \frac{\text{totalBorrowBalance}_{ETH}}{\text{availableBalance}_{ETH} + \text{totalBorrowBalance}_{ETH}}$$

higher totalBorrowBalance, or lower availableBalance in contract higher $U_{ETH} \in [0,1]$

interestRate_{ETH} = BaseRate_{ETH} +
$$\mathbf{U}_{ETH}$$
 × slope_{ETH}

Example: Compound DAI market

Market Liquidity	377,443,771 DAI
# of Suppliers	18468
# of Borrowers	2750
Collateral Factor	83%
cDAI Minted	26,810,077,978
Exchange Rate	1 DAI = 45.26986803778856 cDAI

(Oct. 2022)

Liquidation: debt > BorrowCapacity

If user's health < 1 then <u>anyone</u> can call:

This function transfers liquidator's ETH into ETH market, and gives the liquidator cDAI from user's collateral

Liquidation: debt > BorrowCapacity

If user's health < 1 the **anyone** can call:

lic t) Liquidator is repaying the user's ETH debt and getting the user's cDAI add [at a discounted exchange rate -- penalty for user] set (e.g., ETH)

(e.g., cDAI)

This function transfers liquidator's ETH into ETH market, and gives the liquidator cDAI from user's collateral

What is liquidation risk?

Historical DAI interest rate on Compound (APY):

Demand for DAI spikes

- \implies price of DAI spikes
- \implies user's debt shoots up
- \Rightarrow user's health drops
- \Rightarrow liquidation ...

To use Compound, borrower must constantly monitor APY and quickly repay loans if APY goes too high (can be automated)

Summary & stats

- Liquidity providers can earn interest on their assets
- DeFi lending usage:

Compund outstanding debt

Summary & stats

Compound liquidation statistics:

Caused by collateral price drops or debt APY spikes

Flash loans

What is a flash loan?

A flash loan is taken and repaid in a single transaction

 \Rightarrow zero risk for lender \Rightarrow borrower needs no collateral

(Tx is valid only if funds are returned in same Tx)

'Attacking the DeFi Ecosystem with Flash Loans for Fun and Profit"

Use cases

- Risk free arbitrage
- Collateral swap
- DeFi attacks: price oracle manipulation
 - •
 - ullet
 - \bullet

Risk free arbitrage

Alice finds a USDC/DAI price difference in two pools

Collateral swap

start: Alice @Compound

end goal: Alice @Compound

-1000 DAI +1 cETH Take 1000 DAI flash loan Repay 1000 DAI debt Redeem 1 cETH Swap 1 cETH for 3000 cUSDC Deposit 3000 cUSDC as collateral Borrow 1000 DAI Repay 1000 DAI flash loan

-1000 DAI +3000 cUSDC

borrowed DAI using (a single Ethereum transaction) ETH as collateral borrowed DAI using USDC as collateral

Aave v1 implementation

function flashLoan(address _receiver, uint256 _amount) {

// transfer funds to the receiver
core.transferToUser(_reserve, userPayable, _amount);

// execute action of the receiver
receiver.executeOperation(_reserve, _amount, amountFee, _params);

// abort if loan is not repaid

...

...

Flash loans amounts on Aave (in 2021)

Top 5 Days - Loan Amount	
Date	FALSHLOAN_USD 🔻
May 22	624.5M
May 5	520.9M
May 21	515.0M
May 19	265.7M
Aug 3	163.7M
